

Padé - Rational Polynomial Approximations – Prof. Richard B. Goldstein

Approximate: $f(x) = a_0 + a_1x + \dots + a_Nx^N + \dots$ by $R_{m,n}(x) = \frac{p_0 + p_1x + \dots + p_mx^m}{q_0 + q_1x + \dots + q_nx^n}$ where $N = m + n$

To find the p's and q's (assume $q_0 = 1$) and rearrange: $f(x) \approx \frac{P_m(x)}{Q_n(x)} \Rightarrow \frac{f(x)Q_n(x) - P_m(x)}{Q_n(x)} \approx 0$

in which the numerator's coefficients of 1, x, ..., x^{m+n} are set to 0. This will result in a system of m linear equations in m unknowns involving the q's alone and simple equations for the p's.

Example #1 $f(x) = \tan(x) = x + \frac{1}{3}x^3 + \frac{2}{15}x^5 + \dots$

is accurate to within ± 0.0133 on $[-\pi/4, \pi/4]$. Using **m = 3** and **n = 2**

$$\frac{p_0 + p_1x + p_2x^2 + p_3x^3}{1 + q_1x + q_2x^2} \approx x + \frac{1}{3}x^3 + \frac{2}{15}x^5 + \dots$$

$$p_0 + p_1x + p_2x^2 + p_3x^3 \approx \left(x + \frac{1}{3}x^3 + \frac{2}{15}x^5\right)(1 + q_1x + q_2x^2)$$

Equate the coefficients on both sides:

$$\begin{array}{lcl} 1: & p_0 & = 0 \\ x: & p_1 & = 1 \\ x^2: & p_2 & = q_1 \\ x^3: & p_3 & = \frac{1}{3} + q_2 \\ x^4: & 0 & = q_1 \\ x^5: & 0 & = \frac{2}{15} + \frac{q_2}{3} \end{array}$$

Solve the last two equations first and substitute the q_1 and q_2 to find the p's

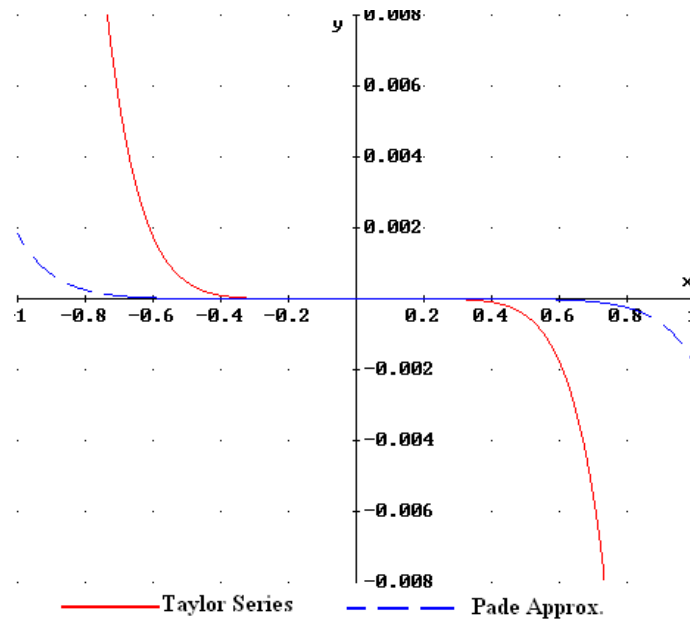

$$q_1 = 0, q_2 = -\frac{2}{5}, p_0 = 0, p_1 = 1, p_2 = 0, p_3 = -\frac{1}{15}$$

$$f(x) \approx \frac{x - \frac{x^3}{15}}{1 - \frac{2x^2}{5}} \text{ is accurate to within } \pm 0.000212 \text{ on } [-\pi/4, \pi/4]$$

Note: Using the Taylor expansion of $\sin(x)$ and $\cos(x)$ one would expect

$$f(x) \approx \frac{x - \frac{x^3}{6}}{1 - \frac{x^2}{2}} \text{ but that is accurate to within } \pm 0.0189 \text{ on } [-\pi/4, \pi/4]$$

Error Curves

If the approximation is repeated with $m = 5$ and $n = 4$, noting the various coefficients that are zero:

$$\frac{p_1x + p_3x^3 + p_5x^5}{1 + q_2x^2 + q_4x^4} \approx x + \frac{1}{3}x^3 + \frac{2}{15}x^5 + \frac{17}{315}x^7 + \frac{62}{2835}x^9 + \dots$$

$$p_1x + p_3x^3 + p_5x^5 + p_7x^7 \approx \left(x + \frac{1}{3}x^3 + \frac{2}{15}x^5 + \frac{17}{315}x^7 + \frac{62}{2835}x^9 \right) (1 + q_2x^2 + q_4x^4)$$

Equate the coefficients on both sides:

$$\begin{aligned} x: \quad p_1 &= 1 \\ x^3: \quad p_3 &= q_2 + \frac{1}{3} \\ x^5: \quad p_5 &= q_4 + \frac{q_2}{3} + \frac{2}{15} \\ x^7: \quad 0 &= \frac{q_4}{3} + \frac{2q_2}{15} + \frac{17}{315} \\ x^9: \quad 0 &= \frac{2q_4}{15} + \frac{17q_2}{315} + \frac{62}{2835} \end{aligned}$$

Solve the last two equations first and substitute the q_2 and q_4 to find the p 's

$$q_2 = -\frac{4}{9}, \quad q_4 = \frac{1}{63}, \quad p_1 = 1, \quad p_3 = -\frac{1}{9}, \quad p_5 = \frac{1}{945}$$

$$f(x) \approx \frac{x - \frac{x^3}{9} + \frac{x^5}{945}}{1 - \frac{4x^2}{9} + \frac{x^4}{63}} \text{ is accurate to within } \pm 1.347 \times 10^{-8} \text{ on } [-\pi/4, \pi/4]$$

Note: The terms in the numerator and denominator are getting closer to the Taylor Series terms for $\sin(x)$ and $\cos(x)$

Example #2

$$f(x) = \ln\left(\frac{1+0.8x}{1-0.2x}\right) = x - \frac{3}{10}x^2 + \frac{13}{75}x^3 - \frac{51}{500}x^4 + \frac{41}{625}x^5 + \dots$$

is accurate within ± 0.02600 on $[0, 1]$. Using $m = 3$ and $n = 2$

$$\frac{p_0 + p_1x + p_2x^2 + p_3x^3}{1 + q_1x + q_2x^2} \approx x - \frac{3}{10}x^2 + \frac{13}{75}x^3 - \frac{51}{500}x^4 + \frac{41}{625}x^5 + \dots$$

$$p_0 + p_1x + p_2x^2 + p_3x^3 \approx \left(x - \frac{3}{10}x^2 + \frac{13}{75}x^3 - \frac{51}{500}x^4 + \frac{41}{625}x^5\right)(1 + q_1x + q_2x^2)$$

Equate the coefficients on both sides:

$$\begin{aligned} 1: \quad p_0 &= 0 \\ x: \quad p_1 &= 1 \\ x^2: \quad p_2 &= -\frac{3}{10} + q_1 \\ x^3: \quad p_3 &= \frac{13}{75} - \frac{3q_1}{10} + q_2 \\ x^4: \quad 0 &= -\frac{51}{500} + \frac{13q_1}{75} - \frac{3q_2}{10} \\ x^5: \quad 0 &= \frac{41}{625} - \frac{51q_1}{500} + \frac{13q_2}{75} \end{aligned}$$

Solve the last two equations first and substitute the q_1 and q_2 to find the p 's

$$q_1 = \frac{18}{5}, q_2 = \frac{87}{50}, p_0 = 0, p_1 = 1, p_2 = \frac{33}{10}, p_3 = \frac{5}{6}$$

$$f(x) \approx \frac{x + 3.3x^2 + 0.8333333\dots x^3}{1 + 3.6x + 1.74x^2} \text{ is accurate within } \pm 0.00126 \text{ on } [0, 1]$$

Note: Since the denominator in the Padé approximation has a root at -0.33 , the approximation is only good for $x > 0$.

Error Curves

Continued Fraction Expansions

$$\frac{2x^2 + 22x + 58}{x^3 + 14x^2 + 60x + 73} = \frac{(2x + 22)x + 58}{((x + 14)x + 60)x + 73} = \frac{2}{x + 3 - \frac{2}{x + 4 + \frac{1}{x + 7}}}$$

The first expression 8 \times , 5 \pm , and 1 \div or 14 ops; the second requires 4 \times , 5 \pm , and 1 \div or 10 ops; and the third requires 5 \pm and 3 \div or only 8 ops.

$$\begin{aligned} \frac{2x^2 + 22x + 58}{x^3 + 14x^2 + 60x + 73} &= \frac{2(x^2 + 11x + 29)}{x^3 + 14x^2 + 60x + 73} = \frac{2}{\frac{x^3 + 14x^2 + 60x + 73}{x^2 + 11x + 29}} \\ &= \frac{2}{x + 3 - \frac{2x + 14}{x^2 + 11x + 29}} = \frac{2}{x + 3 - \frac{2(x + 7)}{x^2 + 11x + 29}} = \frac{2}{x + 3 - \frac{2}{\frac{x^2 + 11x + 29}{x + 7}}} \\ &= \frac{2}{x + 3 - \frac{2}{x + 4 + \frac{1}{x + 7}}} \end{aligned}$$

Algebraic long-division steps:

$$\begin{array}{r} x + 3 \\ x^2 + 11x + 29 \overline{) x^3 + 14x^2 + 60x + 73} \\ \underline{x^3 + 11x^2 + 29x} \\ 3x^2 + 31x + 73 \\ \underline{3x^2 + 33x + 87} \\ -2x - 14 \end{array} \quad \text{and} \quad \begin{array}{r} x + 4 \\ x + 7 \overline{) x^2 + 11x + 29} \\ \underline{x^2 + 7x} \\ 4x + 29 \\ \underline{4x + 28} \\ 1 \end{array}$$
